The Five Dimensions Of Curiosity
How are you curious?
by Todd B. Kashdan, David J. Disabato, Fallon R. Goodman, and Carl Naughton

From Curious To Competent
How to move your people up the learning curve
by Claudio Fernández-Aráoz, Andrew Roscoe and Kentaro Aramaki
Most of the breakthrough discoveries and remarkable inventions throughout history, from flints for starting a fire to self-driving cars, have something in common: They are the result of curiosity. The impulse to seek new information and experiences and explore novel possibilities is a basic human attribute. New research points to three important insights about curiosity as it relates to business. First, curiosity is much more important to an enterprise’s performance than was previously thought. That’s because cultivating it at all levels helps leaders and their employees adapt to uncertain market conditions and external pressures: When our curiosity is triggered, we think more deeply and rationally about decisions and come up with more-creative solutions. In addition, curiosity allows leaders to gain more respect from their followers and inspires employees to develop more-trusting and more-collaborative relationships with colleagues.

Second, by making small changes to the design of their organizations and the ways they manage their employees, leaders can encourage curiosity—and improve their companies. This is true in every industry and for creative and routine work alike.

Third, although leaders might say they treasure inquisitive minds, in fact most stifle curiosity, fearing it will increase risk and inefficiency. In a survey I conducted of more than 3,000 employees from a wide range of firms and industries, only about 24% reported feeling curious in their jobs on a regular basis, and about 70% said they face barriers to asking more questions at work.

In this article I’ll elaborate on the benefits of and common barriers to curiosity in the workplace and then offer five strategies that can help leaders get high returns on investments in employees’ curiosity and in their own.

THE BENEFITS OF CURIOSITY
New research reveals a wide range of benefits for organizations, leaders, and employees.

Fewer decision-making errors.

In my research I found that when our
sought the most information from showed that the most curious employees various aspects of their work. The results in, the employees were surveyed about they began their new jobs. Four weeks things, measured their curiosity before recruited about 200 employees working in various companies and industries. Twice a week for four weeks, half of them received a text message at the start of their workday that read, “What is one topic or activity you are curious about today? What is one thing you usually take for granted that you want to ask about? Please make sure you ask a few ‘Why questions’ as you engage in your work throughout the day. Please set aside a few minutes to identify how you’ll approach your work today with these questions in mind.”

The other half (the control group) received a message designed to trigger reflection but not raise their curiosity: “What is one topic or activity you’ll engage in today? What is one thing you usually work on or do that you’ll also complete today? Please make sure you think about this as you engage in your work throughout the day. Please set aside a few minutes to identify how you’ll approach your work today with these questions in mind.”

After four weeks, the participants in the first group scored higher than the others on questions assessing their innovative behaviors at work, such as whether they had made constructive suggestions for implementing solutions to pressing organizational problems.

When we are curious, we view tough situations more creatively. Studies have found that curiosity is associated with less defensive reactions to stress and less aggressive reactions to provocation. We also perform better when we’re curious. In a study of 120 employees I found that natural curiosity was associated with better job performance, as evaluated by their direct bosses.

Reduced group conflict. My research found that curiosity encourages members of a group to put themselves in one another’s shoes and take an interest in one another’s ideas rather than focus only on their own perspective. That causes them to work together more effectively and smoothly: Conflicts are less heated, and groups achieve better results.

More-open communication and better team performance. Working with executives in a leadership program at Harvard Kennedy School, my colleagues and I divided participants into groups of five or six, had some groups participate in a task that heightened their curiosity, and then asked all the groups to engage in a simulation that tracked performance. The groups whose curiosity had been heightened performed better than the control groups because they shared information more openly and listened more carefully.

The Problem

Two barriers to curiosity

Despite the well-established benefits of curiosity, organizations often discourage it. This is not because leaders don’t see its value. On the contrary, both leaders and employees understand that curiosity creates positive outcomes for their companies. In the survey of more than 3,000 employees mentioned earlier, 92%
When we are curious, we view tough situations more creatively and have less defensive reactions to stress.

credited curious people with bringing new ideas into teams and organizations and viewed curiosity as a catalyst for job satisfaction, motivation, innovation, and high performance.

Yet executives’ actions often tell a different story. True, some organizations, including 3M and Facebook, give employees free time to pursue their interests, but they are rare. And even in such organizations, employees often have challenging short-term performance goals (such as meeting a quarterly sales target or launching a new product by a certain date) that consume the “free time” they could have spent exploring alternative approaches to their work or coming up with innovative ideas.

Two tendencies restrain leaders from encouraging curiosity:

**They have the wrong mindset about exploration.** Leaders often think that letting employees follow their curiosity will lead to a costly mess. In a recent survey I conducted of 520 chief learning officers and chief talent development officers, I found that they often shy away from encouraging curiosity because they believe the company would be harder to manage if people were allowed to explore their own interests. They also believe that disagreements would arise and making and executing decisions would slow down, raising the cost of doing business. Research finds that although people list creativity as a goal, they frequently reject creative ideas when actually presented with them. That’s understandable: Exploration often involves questioning the status quo and doesn’t always produce useful information. But it also means not settling for the first possible solution—and so it often yields better remedies.

**They seek efficiency to the detriment of exploration.** In the early 1900s Henry Ford focused all his efforts on one goal: reducing production costs to create a car for the masses. By 1908 he had realized that vision with the introduction of the Model T. Demand grew so high that by 1921 the company was producing 56% of all passenger cars in the United States—remarkable success made possible primarily by the firm’s efficiency-centered model of work. But in the late 1920s, as the U.S. economy rose to new heights, consumers started wanting greater variety in their cars. While Ford remained fixated on improving the Model T, competitors such as General Motors started producing an array of models and soon captured the main share of the market. Owing to its single-minded focus on efficiency, Ford stopped experimenting and innovating and fell behind.

These leadership tendencies help explain why our curiosity usually declines the longer we’re in a job. In one survey, I asked about 250 people who had recently started working for various companies a series of questions designed to measure curiosity; six months later I administered a follow-up survey. Although initial levels of curiosity varied, after six months everyone’s curiosity had dropped, with the average decline exceeding 20%. Because people were under pressure to complete their work quickly, they had little time to ask questions about broad processes or overall goals.

**FIVE WAYS TO BOLSTER CURIOSITY**

It takes thought and discipline to stop stifling curiosity and start fostering it. Here are five strategies leaders can employ.

1. **Hire for curiosity.**
To identify potential employees who are T-shaped, IDEO pays attention to how candidates talk about past projects. Someone who focuses only on his or her own contributions may lack the breadth to appreciate collaboration. T-shaped candidates are more likely to talk about how they succeeded with the help of others and to express interest in working collaboratively on future projects.

To assess curiosity, employers can also ask candidates about their interests outside of work. Reading books unrelated to one’s own field and exploring questions just for the sake of knowing the answers are indications of curiosity. And companies can administer curiosity assessments, which have been validated in a myriad of studies. These generally measure whether people explore things they don’t know, analyze data to uncover new ideas, read widely beyond their field, have diverse interests outside work, and are excited by learning opportunities.

It’s also important to remember that the questions candidates ask—not just the answers they provide—can signal curiosity. For instance, people who want to know about aspects of the organization that aren’t directly related to the job at hand probably have more natural curiosity than people who ask only about the role they would perform.

2 Model inquisitiveness.

Leaders can encourage curiosity throughout their organizations by being inquisitive themselves. In 2000, when Greg Dyke had been named director general of the BBC but hadn’t yet assumed the position, he spent five months visiting the BBC’s major locations, assembling the staff at each stop. Employees expected a long presentation but instead got a simple question: “What is the one thing I should do to make things better for you?” Dyke would listen carefully and then ask, “What is the one thing I should do to make things better for our viewers and listeners?”

The BBC’s employees respected their new boss for taking the time to ask questions and listen. Dyke used their responses to inform his thinking about the changes needed to solve problems facing the BBC and to identify what to work on first. After officially taking the reins, he gave a speech to the staff that reflected what he had learned and showed employees that he had been truly interested in what they said.

By asking questions and genuinely listening to the responses, Dyke modeled the importance of those behaviors. He also highlighted the fact that when we are exploring new terrain, listening is as important as talking: It helps us fill gaps in our knowledge and identify other questions to investigate.

That may seem intuitive, but my research shows that we often prefer to talk rather than to listen with curiosity. For instance, when I asked some 230 high-level leaders in executive education classes what they would do if confronted with an organizational crisis stemming from both financial and cultural issues, most said they would take action: move to stop the financial bleeding and introduce initiatives to refresh the culture. Only a few said they would ask questions rather than simply impose their ideas on others. Management books commonly encourage leaders assuming new positions to communicate their vision from the start rather than ask employees how they can be most helpful. It’s bad advice.

Why do we refrain from asking questions? Because we fear we’ll be judged incompetent, indecisive, or unintelligent. Plus, time is precious, and we don’t want to bother people. Experience and expertise exacerbate the problem: As people climb the organizational ladder, they think they have less to learn. Leaders also tend to believe they’re expected to talk and provide answers, not ask questions.

Such fears and beliefs are misplaced, my recent research shows. When we demonstrate curiosity about others by asking questions, people like us more and view us as more competent, and the heightened trust makes our relationships more interesting and intimate. By asking questions, we promote more-meaningful connections and more-creative outcomes.

Another way leaders can model curiosity is by acknowledging when they don’t know the answer; that makes it clear that it’s OK to be guided by curiosity. Patricia Fili-Krushel told me that when she joined WebMD Health as chief executive, she met with a group of male engineers in Silicon Valley. They were doubtful that she could add value to their work and, right off the bat, asked what she knew about engineering. Without hesitation, Fili-Krushel made a zero with her fingers. “This is how much I know about engineering,” she told them. “However, I do know how to run businesses, and I’m hoping you can teach me what I need to know about your world.” When leaders concede that they don’t have the answer to a question, they show that they value the process of looking for answers and motivate others to explore as well.

New hires at Pixar Animation Studios are often hesitant to question the status quo, given the company’s track record of hit movies and the brilliant work of those who have been there for years. To combat that tendency, Ed Catmull, the cofounder and
president, makes a point of talking about times when Pixar made bad choices. Like all other organizations, he says, Pixar is not perfect, and it needs fresh eyes to spot opportunities for improvement (see “How Pixar Fosters Collective Creativity,” HBR, September 2008). In this way Catmull gives new recruits license to question existing practices. Recognizing the limits of our own knowledge and skills sends a powerful signal to others.

Tenelle Porter, a postdoctoral scholar in psychology at the University of California, Davis, describes intellectual humility as the ability to acknowledge that what we know is sharply limited. As her research demonstrates, higher levels of intellectual humility are associated with a greater willingness to consider views other than our own. People with more intellectual humility also do better in school and at work. Why? When we accept that our own knowledge is finite, we are more apt to see that the world is always changing and that the future will diverge from the present. By embracing this insight, leaders and employees can begin to recognize the power of exploration.

Finally, leaders can model inquisitiveness by approaching the unknown with curiosity rather than judgment. Bob Langer, who heads one of MIT’s most productive laboratories, told me recently that this principle guides how he manages his staff. As human beings, we all feel an urge to evaluate others—often not positively. We’re quick to judge their ideas, behaviors, and perspectives, even when those relate to things that haven’t been tried before. Langer avoids this trap by raising questions about others’ ideas, which leads people to think more deeply about their perspective and to remain curious about the tough problems they are trying to tackle. In doing so, he is modeling behavior that he expects of others in the lab.
Emphasize learning goals.

When I asked Captain Chesley “Sully” Sullenberger how he was able to land a commercial aircraft safely in the Hudson River, he described his passion for continuous learning. Although commercial flights are almost always routine, every time his plane pushed back from the gate he would remind himself that he needed to be prepared for the unexpected. “What can I learn?” he would think. When the unexpected came to pass, on a cold January day in 2009, Sully was able to ask himself what he could do, given the available options, and come up with a creative solution. He successfully fought the tendency to grasp for the most obvious option (landing at the nearest airport). Especially when under pressure, we narrow in on what immediately seems the best course of action. But those who are passionate about continuous learning contemplate a wide range of options and perspectives. As the accident report shows, Sully carefully considered several alternatives in the 208 seconds between his discovery that the aircraft’s engines lacked thrust and his landing of the plane in the Hudson.

It’s natural to concentrate on results, especially in the face of tough challenges. But focusing on learning is generally more beneficial to us and our organizations, as some landmark studies show. For example, when U.S. Air Force personnel were given a demanding goal for the number of planes to be landed in a set time frame, their performance decreased. Similarly, in a study led by Southern Methodist University’s Don VandeWalle, sales professionals who were naturally focused on performance goals, such as meeting their targets and being seen by colleagues as good at their jobs, did worse during a promotion of a product (a piece of medical equipment priced at about $5,400) than reps who were naturally...
focused on learning goals, such as exploring how to be a better salesperson. That cost them, because the company awarded a bonus of $300 for each unit sold.

A body of research demonstrates that framing work around learning goals (developing competence, acquiring skills, mastering new situations, and so on) rather than performance goals (hitting targets, proving our competence, impressing others) boosts motivation. And when motivated by learning goals, we acquire more-diverse skills, do better at work, get higher grades in college, do better on problem-solving tasks, and receive higher ratings after training. Unfortunately, organizations often prioritize performance goals.

Leaders can help employees adopt a learning mindset by communicating the importance of learning and by rewarding people not only for their performance but for the learning needed to get there. Deloitte took this path: In 2013 it replaced its performance management system with one that tracks both learning and performance. Employees meet regularly with a coach to discuss their development and learning along with the support they need to continually grow.

Leaders can also stress the value of learning by reacting positively to ideas that may be mediocre in themselves but could be springboards to better ones. Writers and directors at Pixar are trained in a technique called “plussing,” which involves building on ideas without using judgmental language. Instead of rejecting a sketch, for example, a director might find a starting point by saying, “I like Woody’s eyes, and what if we...?” Someone else might jump in with another “plus.” This technique allows people to remain curious, listen actively, respect the ideas of others, and contribute their own. By promoting a process that allows all sorts of ideas to be explored, leaders send a clear message that learning is a key goal even if it doesn’t always lead to success.

**Let employees explore and broaden their interests.**

Organizations can foster curiosity by giving employees time and resources to explore their interests. One of my favorite examples comes from my native country. It involves Italy’s first typewriter factory, Olivetti, founded in 1908 in the foothills of the Italian Alps. In the 1930s some employees caught a coworker leaving the factory with a bag full of iron pieces and machinery. They accused him of stealing and asked the company to fire him. The worker told the CEO, Adriano Olivetti, that he was taking the parts home to work on a new machine over the weekend because he didn’t have time while performing his regular job. Instead of firing him, Olivetti gave him time to create the machine and charged him with overseeing its production. The result was Divisumma, the first electronic calculator. Divisumma sold well worldwide in the 1950s and 1960s, and Olivetti promoted the worker to technical director. Unlike leaders who would have shown him the door, Olivetti gave him the space to explore his curiosity, with remarkable results.

Some organizations provide resources to support employees’ outside interests. Since 1996 the manufacturing conglomerate United Technologies (UTC) has given as much as $12,000 in tuition annually to any employee seeking a degree part-time—no strings attached. Leaders often don’t want to invest in training employees for fear that they will jump to a competitor and take their expensively acquired skills with them. Even though UTC hasn’t tried to quantify the benefits of its tuition reimbursement program, Gail Jackson, the vice president of human resources when we spoke, believes in the importance of curious employees. “It’s better to train and have them leave than not to train and have them stay,” she told me. But according to the Society for Human Resource Management’s 2017 employee benefits report, only 44% of organizations provide or support cross-training to develop skills not directly related to workers’ jobs.

Leaders might provide opportunities for employees to travel to unfamiliar locales. When we have chances to expand our interests, research has found, we not only remain curious but also become more confident about what we can accomplish and more successful at work. Employees can “travel” to other roles and areas of the organization to gain a broader perspective. At Pixar, employees across the organization can provide “notes”—questions and advice—that help directors consider all sorts of possibilities for the movies they are working on.

Employees can also broaden their interests by broadening their networks. Curious people often end up being star performers thanks to their diverse networks, my research with the University of Toronto’s Tiziana Casciaro, Bill McEvily, and Evelyn Zhang finds. Because they’re more comfortable than others asking questions, such people more easily create and nurture ties at work—and those ties are critical to their career development and success. The organization benefits when employees are connected to people who can help them with challenges and motivate them to go the extra mile. MIT’s Bob Langer works to raise curiosity in his students by introducing them to experts in his network. Similarly, by connecting people across organizational departments and units, leaders can encourage employees to be curious about their colleagues’ work and ways of doing business.

Deliberate thinking about workspaces can broaden networks and encourage the
Leaders can stress the value of learning by reacting positively to mediocre ideas that could be springboards to better ones.

cross-pollination of ideas. In the 1990s, when Pixar was designing a new home for itself in Emeryville, across the bay from San Francisco, the initial plans called for a separate building for each department. But then-owner Steve Jobs had concerns about isolating the various departments and decided to build a single structure with a large atrium in the center, containing employee mailboxes, a café, a gift shop, and screening rooms. Forcing employees to interact, he reasoned, would expose them to one another’s work and ideas.

Leaders can also boost employees’ curiosity by carefully designing their teams. Consider Massimo Bottura, the owner of Osteria Francescana, a three-Michelin-star restaurant in Modena, Italy, that was rated the Best Restaurant in the World in 2016 and 2018. His sous chefs are Davide di Fabio, from Italy, and Kondo Takahiko, from Japan. The two differ not only in their origins but also in their strengths: Di Fabio is more comfortable with improvisation, while Takahiko is obsessed with precision. Such “collisions” make the kitchen more innovative, Bottura believes, and inspire curiosity in other workers.

Have “Why?” “What if...?” and “How might we...?” days.

The inspiration for the Polaroid instant camera was a three-year-old’s question. Inventor Edwin Land’s daughter was impatient to see a photo her father had just snapped. When he explained that the film had to be processed, she wondered aloud, “Why do we have to wait for the picture?”

As every parent knows, Why? is ubiquitous in the vocabulary of young children, who have an insatiable need to understand the world around them. They aren’t afraid to ask questions, and they don’t worry about whether others believe they should already know the answers. But as children grow older, self-consciousness creeps in, along with the desire to appear confident and maintain a sense of wonder is crucial to maintaining a sense of wonder is crucial to employees’ curiosity to fuel learning and innovation. The most effective leaders help employees innovate by challenging existing processes that managers had already defined. For the other half, the information was presented as the “go back method”—our version of a control condition. We encouraged that group to view those elements as immutable, and we stressed the importance of following existing processes that managers had already defined. For the other half, the information was presented as the “go back method.” We encouraged those employees to see the elements as fluid and to “go back” and rethink them. A week later we found that the workers who’d read about the “go back method” showed more creativity in tasks than the workers in the “grow method” group. They were more open to others’ ideas and worked more effectively with one another.

To encourage curiosity, leaders should also teach employees how to ask good questions. Bob Langer has said he wants to “help people make the transition from giving good answers to asking good questions” (see “The Edison of Medicine,” HBR, March–April 2017). He also tells his students that they could change the world, thus boosting the curiosity they need to tackle challenging problems.

Organizing “Why?” days, when employees are encouraged to ask that question if facing a challenge, can go a long way toward fostering curiosity. Intellectual Ventures, a company that generates inventions and buys and licenses patents, organizes “invention sessions” in which people from different disciplines, backgrounds, and levels of expertise come together to discuss potential solutions to tough problems, which helps them consider issues from various angles (see “Funding Eureka!” HBR, March 2010). Similarly, under Toyota’s 5 Whys approach, employees are asked to investigate problems by asking Why? After coming up with an answer, they are to ask why that’s the case, and so on until they have asked the question five times. This mindset can help employees innovate by challenging existing perspectives.

IN MOST ORGANIZATIONS, leaders and employees alike receive the implicit message that asking questions is an unwanted challenge to authority. They are trained to focus on their work without looking closely at the process or their overall goals. But maintaining a sense of wonder is crucial to creativity and innovation. The most effective leaders look for ways to nurture their employees’ curiosity to fuel learning and discovery.

FRANCESCO GINO is the Tandon Family Professor of Business Administration at Harvard Business School and the author of the books Rebel Talent: Why It Pays to Break the Rules at Work and in Life and Sidetracked: Why Our Decisions Get Derailed, and How We Can Stick to the Plan.
THE FIVE DIMENSIONS OF CURIOSITY

TODD B. KASHDAN | DAVID J. DISABATO | FALLON R. GOODMAN | CARL NAUGHTON
Psychologists have compiled a large body of research on the many benefits of curiosity. It enhances intelligence: In one study, highly curious children aged three to 11 improved their intelligence test scores by 12 points more than their least-curious counterparts did. It increases perseverance, or grit: Merely describing a day when you felt curious has been shown to boost mental and physical energy by 20% more than recounting a time of profound happiness. And curiosity propels us toward deeper engagement, superior performance, and more-meaningful goals: Psychology students who felt more curious than others during their first class enjoyed lectures more, got higher final grades, and subsequently enrolled in more courses in the discipline.

But another stream of research on curiosity is equally important, in our view. Since the 1950s psychologists have offered competing theories about what makes one person more curious than another. Rather than regard curiosity as a single trait, we can now break it down into five distinct dimensions. Instead of asking, “How curious are you?” we can ask, “How are you curious?”

A BRIEF HISTORY
In the 1950s Daniel Berlyne was one of the first psychologists to offer a comprehensive model of curiosity. He argued that we all seek the sweet spot between two deeply uncomfortable states: understimulation (coping with tasks, people, or situations that lack sufficient novelty, complexity, uncertainty, or conflict) and overstimulation. To that end we use either what Berlyne called “diversive curiosity” (as when a bored person searches for something—anything—to boost arousal) or what he called “specific curiosity” (as when a hyperstimulated person tries to understand what’s happening in order to reduce arousal to a more manageable level).

Building on Berlyne’s insights, in 1994 George Loewenstein, of Carnegie Mellon University, proposed the “information gap” theory. He posited that people become curious upon realizing that they lack desired knowledge; this creates an aversive feeling of uncertainty, which compels them to uncover the missing information.

How Are You Curious?

Use this scale to indicate the degree to which the following statements describe you:
1. Does not describe me at all. 2. Barely describes me. 3. Somewhat describes me. 4. Neutral. 5. Generally describes me. 6. Mostly describes me. 7. Completely describes me.

DEPRIVATION SENSITIVITY
Thinking about solutions to difficult conceptual problems can keep me awake at night.  
I can spend hours on a single problem because I just can’t rest without knowing the answer.  
I feel frustrated if I can’t figure out the solution to a problem, so I work even harder to solve it.  
I work relentlessly at problems that I feel must be solved.  
It frustrates me to not have all the information I need.

JOYOUS EXPLORATION
I view challenging situations as an opportunity to grow and learn.  
I am always looking for experiences that challenge how I think about myself and the world.  
I seek out situations where it is likely that I will have to think in depth about something.  
I enjoy learning about subjects that are unfamiliar to me.  
I find it fascinating to learn new information.

SOCIAL CURIOUSITY
I like to learn about the habits of others.  
I like finding out why people behave the way they do.  
When other people are having a conversation, I like to find out what it’s about.  
When around other people, I like listening to their conversations.  
When people quarrel, I like to know what’s going on.

STRESS TOLERANCE
The smallest doubt can stop me from seeking out new experiences.  
I cannot handle the stress that comes from entering uncertain situations.  
I find it hard to explore new places when I lack confidence in my abilities.  
I cannot function well if I am unsure whether a new experience is safe.  
It is difficult to concentrate when there is a possibility that I will be taken by surprise.

THRILL SEEKING
The anxiety of doing something new makes me feel excited and alive.  
Risk taking is exciting to me.  
When I have free time, I want to do things that are a little scary.  
Creating an adventure as I go is much more appealing than a planned adventure.  
I prefer friends who are excitingly unpredictable.

Scoring instructions: Compute the average score for each dimension (reverse score the items under stress tolerance). By comparing your results with those of a nationally representative sample of people in the United States, you can determine whether you are low, medium, or high on each dimension. See the next page to interpret your scores.
But these theories, focused on our inherent desire to reduce tension, don’t explain other expressions of curiosity: tourists strolling through a museum, entrepreneurs poring over feedback from beta testing, people engrossed in a book. The University of Rochester’s Edward Deci addressed those in the 1970s, arguing that curiosity also reflects our intrinsic motivation “to seek out novelty and challenges, to extend and exercise one’s capacities, to explore, and to learn.” We use it not just to avoid discomfort but to generate positive experiences.

In another body of work, the University of Delaware psychologist Marvin Zuckerman spent five decades (from the 1960s to the 2000s) studying sensation seeking, or people’s interest in how other experiences. And in 2006 the psychologist Britta Renner, of the University of Konstanz, initiated the study of social curiosity, or people’s interest in how other individuals think, feel, and behave.

THE FIVE-DIMENSIONAL MODEL

Synthesizing this and other important research, and in conjunction with our George Mason colleague Patrick McKnight, we created a five-dimensional model of curiosity. The first dimension, derived from Berlyne and Loewenstein’s work, is deprivation sensitivity—recognizing a gap in knowledge the filling of which offers relief. This type of curiosity doesn’t necessarily feel good, but people who experience it work relentlessly to solve problems.

The second dimension, influenced by Deci’s research, is joyous exploration—being consumed with wonder about the fascinating features of the world. This is a pleasurable state; people in it seem to possess a joie de vivre.

The third dimension, stemming from Renner’s research, is social curiosity—talking, listening, and observing others to learn what they are thinking and doing. Human beings are inherently social animals, and the most effective and efficient way to determine whether someone is friend or foe is to gain information. Some may even snoop, eavesdrop, or gossip to do so.

The fourth dimension, which builds on recent work by Paul Silvia, a psychologist at the University of North Carolina at Greensboro, is stress tolerance—a willingness to accept and even harness the anxiety associated with novelty. People lacking this ability see information gaps, experience wonder, and are interested in others but are unlikely to step forward and explore.

The fifth dimension, inspired by Zuckerman, is thrill seeking—being willing to take physical, social, and financial risks to acquire varied, complex, and intense experiences. For people with this capacity, the anxiety of confronting novelty is something to be amplified, not reduced.

We have been testing this model in several ways. With Time Inc. we conducted surveys across the United States to discover which of the dimensions lead to the best outcomes and generate particular benefits. For instance, joyous exploration has the strongest link with the experience of intense positive emotions. Stress tolerance has the strongest link with satisfying the need to feel competent, autonomous, and that one belongs. Social curiosity has the strongest link with being a kind, generous, modest person.

With Merck KGaA we have explored attitudes toward and expressions of work-related curiosity. In a survey of 3,000 workers in China, Germany, and the United States, we found that 84% believe that curiosity catalyzes new ideas, 74% think it inspires unique, valuable talents, and 63% think it helps one get promoted.

In other studies across diverse units and geographies, we have found evidence that four of the dimensions—joyous exploration, deprivation sensitivity, stress tolerance, and social curiosity—improve work outcomes. The latter two seem to be particularly important: Without the ability to tolerate stress, employees are less likely to seek challenges and resources and to voice dissent and are more likely to feel enervated and to disengage. And socially curious employees are better at others at resolving conflicts with colleagues, more likely to receive social support, and more effective at building connections, trust, and commitment on their teams. People or groups high in both dimensions are more innovative and creative.

A monolithic view of curiosity is insufficient to understand how that quality drives success and fulfillment in work and life. To discover and leverage talent and to form groups that are greater than the sum of their parts, a more nuanced approach is needed.

FROM CURIOUS TO COMPETENT

CLAUDIO FERNÁNDEZ-ARÁOZ | ANDREW ROSCOE | KENTARO ARAMAKI

or 30 years our executive search firm has been in the business of assessing leaders along two broad dimensions: potential and competence. One key conclusion? You can’t have either without curiosity.

Although we have found that high potentials also need insight, engagement, and determination, curiosity—defined as a penchant for seeking new experiences, knowledge, and feedback and an openness to change—is perhaps most important. In fact, in analyzing exactly how leaders develop, we’ve found that curiosity—which we assess on a four-point scale, from emerging to extraordinary, using interviews and reference checks—is the best predictor of strength in all seven of the leadership competencies we measure (results orientation, strategic orientation, collaboration and influence, team leadership, developing organizational capabilities, change leadership, and market understanding).

We’ve also found that executives with extraordinary curiosity are usually able, with the right development, to advance to C-level roles. However, that development is critical. Although a strong positive correlation exists between curiosity and competence, there is a significant spread—and a highly curious executive may score much lower on competence than less curious counterparts.

How can organizations help people make the leap from curious to competent? Studying our global database of information on executives’ backgrounds, experiences, potential, and competence, we came up with an answer: by providing the right types of stretch assignments and job rotations.

Consider the cases of 20 actual general managers. All were rated as extraordinarily curious, yet only half reached the top level of competence; the other half were at the bottom. What separated the two groups was the complexity and breadth of the opportunities they’d been given, as shown in the first graph below. The top 10 executives had worked for more companies, been exposed to more diverse customers, worked abroad or with colleagues from other cultures, dealt with more business scenarios (start-ups, rapid growth, M&A, integration, downsizing, turnarounds), and managed more people. When curious people are given these experiences, they shine. When they aren’t, they either stagnate or jump ship. While most of the low-competence managers had worked for just one company, the outstanding ones had worked for more than three.

Note, too, that although our potential and competence models hold true around the world, not all cultures achieve the same competence return on curiosity, as depicted in the second graph below. For example, although the Japanese have lots of curiosity, their competence scores are barely average. The British, by contrast, are less curious but more competent. Why these differences? We believe that Japan’s cultural norms limit people’s development by rewarding tenure above all and by discouraging big job moves. Meanwhile, British firms embrace company and role changes along with coaching. This is yet more evidence that although curiosity is a necessary ingredient for executive success, in itself it’s not enough.

Experiences That Transform Curiosity into Competence

Consider 20 leaders, all rated as extraordinarily curious. Ten leveraged that into high competence scores (represented by blue bars); 10 did not (gray bars). What made the difference? The extent to which they were given the opportunities below.

The top 10 had:

- Worked for more companies
- Served more diverse customers
- Worked abroad or on a multicultural team
- Experienced more business scenarios
- Managed larger teams

The top 10 had:

- Worked for just one company
- Served fewer, but more stable, customers
- Worked in a single industry or with colleagues from the same culture
- Experienced fewer business scenarios
- Managed smaller teams

The Curiosity-Competence Link Across Six National Cultures

In many countries, executives’ average scores on curiosity (measured on a scale of one to four) and competence (one to seven) come in at similar levels. But Japan and the UK are outliers. In the former, high curiosity does not yield high competence. In the latter, low curiosity does not stop leaders from being highly competent. Cultural norms that prevent (Japan) or encourage (the UK) big job moves may be one reason.
